Tarantula Nebula: Found in the Large Magellanic Cloud 160,000 light years away, 30 Doradus is a massive star forming region.
(Credit: NASA/CXC/Penn State/L.Townsley, et al.)

Caption: The Chandra image of the Tarantula Nebula gives scientists a close-up view of the drama of star formation and evolution. The Tarantula, also known as 30 Doradus, is in one of the most active star-forming regions in a galaxy close to the Milky Way. Massive stars in 30 Doradus are producing intense radiation and searing winds of multimillion-degree gas that carve out gigantic super-bubbles in the surrounding gas. Other massive stars have raced through their evolution and exploded catastrophically as supernovas, leaving behind pulsars and expanding remnants that trigger the collapse of giant clouds of dust and gas to form new generations of stars.

Scale: Image is 24 arcmin across.
